TITLE: The effect of superfine grinding on solid
phase reactions

PERIODICAL: Zhurnal prikladnoy khimii, v. 36, no. 1,
1963, 95 - 101

TEXT: A brief review of solid phase reactions is
first given, concluding that sintering processes occur as a result
of mass exchange in the solid and particularly in the liquid and
gaseous phases. Vibration and jet grinders are considered to be
most effective. To study the sintering reactions of some ore con-
centrates the authors used superfine grinding to ensure a large
reactive area, and further ground the fines together to ensure
maximum intermixing. The grain size was of the order of 1μ . Such
treatment allows the reactions to go almost to completion at tem-
peratures considerably below the usual temperature used for such

Card 1/2

processes. A few examples are quoted including the decomposition of $ZrSiO_4$ (a) in presence of mineralizers (at 1050 - 1100°C) and (b) after superfine grinding, with a mineralizer (98 - 99 % decomposition at 800 - 900°C). The effect of mineralizers are discussed and the importance of intimate mixing is underlined, quoting the decomposition of zircon in the presence of $CaCO_3/CaF_2$. Solid phase reactions of spodumene with $CaCO_3$ or CaO (reactants ground to 1 μ and mixed in a vibration grinder) took place largely at 820°C, in contrast to ~970°C when the grain size was 70 μ . The products were in a freely flowing form (grain size 0.2 - 1 mm), well suitable therefore to continuous production. Detailed study of such reactions should shed light on the complex mechanisms of solid phase processes. There are 2 figures.

TITLE:

Study of the Process of Decomposition of Zircon by
Roasting With Lime

PERIODICAL: Tsvetnyye metally, 1961, ^{vol. 34} No. 6, pp. 59-61

TEXT: At the Second International Atomic Energy Conference (Geneva, 1958) the authors reported on the possibility of improving the recovery of rare metals, including Zr, by increasing the surface area of the ores and concentrates and addition of activating fluoride compounds. In this paper more detailed information is given relating to roasting Zr concentrates. Experiments were carried out to try to decrease the temperature of roasting and to increase the efficiency. The effect of grinding the concentrate and additions of fluoride compounds, with less than 1 to 1.5% iron and titanium oxides and about 2.5% alumina. Grinding was carried out on a three litre steel ball mill. Charges of 50 to 500 g were heated in a laboratory muffle furnace. The quantity of fluorides added varied from 5 to 50 wt.% of the original concentrate. The degree of decomposition was measured by Card 1/4

S/136/61/000/006/001/003

Study of the Process ...

the zirconium content in the residue after treatment with weak hydrochloric and afterwards sulphuric acid. Experiments were carried out with 1.75 parts by weight of calcium carbonate and 1 part by weight of concentrate. Fig.1 shows the effect of additions of CaF_2 (continuous curves) and Na_2SiF_6 (discontinuous curves) on the degree of decomposition, % (curve 1, 900°C ; curve 2, 800°C). The maximum recovery is obtained at 900°C by an addition of 20% CaF_2 or 15% Na_2SiF_6 . Fig.2 shows curves of degree of decomposition against the CaF_2 or Na_2SiF_6 content at 900°C , curve 1 being with a mean grain size of 1μ and curve 2 0.1 mm . The degree of recovery is 99% with 10% Na_2SiF_6 and 97% with 15% CaF_2 when the concentrate has a grain size of 1μ . The method of mixing the charge was also shown to have an effect on the degree of recovery. Fig.3 shows the degree of decomposition against temperature. Curve 1 is after mixing in a vibratory-mill and curve 2 after mixing by hand. The former gives 10 to 20% higher recovery because of more uniform distribution of the components. There are 3 figures and 6 references: 5 Soviet and 1 non-Soviet. The reference to English language publication reads

electrophoresis. At the end of 2-3 days the volume of the circulating plasma increased above the original level, and the protein concentration reached 80-90%; the albumins and most of the globulin content increased rapidly. Following this, a decrease or a slower secondary increase was noted. The excessive increase of the proteins took place mainly in the values of the α_1 -, α_2 -, (β_1 + γ)-globulins; their value reached 200-230% of the original values. The γ - and β_2 -globulins of the serum were restored much slower. The albumin content reached original values within 48 hours. It is apparent that the inflow of albumins into the blood

TITLE:

Electrophoretic Investigation of Phospholipase C (Elektroforeticheskoye issledovaniye fosfolipazy C)

PERIODICAL:

Doklady AN SSSR, 1957, Vol. 117, Nr 3, pp. 466 - 469 (USSR)

ABSTRACT:

Phospholipase C is one of the pathologically most active exotoxins of the bacterium of the human gasgangrene (Clostridium perfringens). Up to now this ferment could not be isolated in a pure state, and its molecular weight only recently could be defined (reference 3) by means of the radiation inactivation. It was the task of the here described experiments, to obtain an electrophoretic characterization of the phospholipase C by the means of zonal electrophoresis, as well as further to clean the ferment by electrophoretic fractionating. 5 preparations of the enzyme (Varshavskiy-1 and -2, TF-1 and -2, from Moscow, as well as the preparation of the α -toxin of the Cl. perfringens TsIEM, Moscow), were investigated. Furthermore, a preparation of the Cl. oedematiens original Nr 4 Ts IEM was proved. The Moscow preparations were 7, respectively 8,5 years old. The method of investigation is described here. According to their specific activity both Varshavskiy-preparations and the TsIEM were equal. They exceed TF-1 and -2 5-fold (table 1). The activity

Card 1/3

20-3-30/52

Electrophoretic Investigation of Phospholipase C

of the enzyme of C1. oedematiens was at least 100-fold weaker. The results of the electrophoretic fractionating are recorded graphically on tables 1 - 3, From the obtained results it follows: 1.) Phospholipase C of the Varshavskiy-preparations behave like an electrophoretic homogeneous block with a mobility approximated to zero (at pH 8,6). The ferment of the Moscow preparations is electrophoretically heterogeneous. 2.) Phospholipase C of the Varshavskiy preparations after an electrophoretic fractionating entirely retain their original activity (in dissolved state). The enzyme of the Moscow preparations in the course of the experiment renders inactive (up to 70 % at TF-2). 3.) At fractional distillation of the Varshavskiy preparations a 26-fold cleansing of the isoelectric form of the phospholipase C with 50 % of the yield (referred to the total activity of the electrophoretically treated preparations) was obtained. At the occasion of such a fractionating of the Moscow preparations, previously cleansed 5 times by ethanol fractionating, a 18,5-fold total cleansing of the isoelectric form of the enzyme (with a yield of only 1,5 %) was obtained; the same succeeded for the negatively charged form of the ferment with an electrophoretic mobility near to $-2,5 \cdot 10^{-5} \text{ cm}^2/\text{sec}^{-1} \cdot \text{V}^{-1}$ 17-fold (yield 7 %). The electrophoregram of the phospholipase C of

Card 2/3

20-3-30/52

An Electrophoretic Investigation of Phospholipase C

Cl. oedematiens has 2 culminating points (tops). The main top of the phospholipase-C-activity corresponds to a protein of a high anode-mobility = $-6,5 \cdot 10^{-5} \text{ cm}^2/\text{sec.}^{-1} \cdot \text{V}^{-1}$. In the range of the zero-mobility the active protein is absent. That shows a new difference of species of the phospholipase C from Cl. perfringens and Cl. oedematiens. The peculiar difference of phospholipase C of the Moscow preparations of the α -toxin of Cl. perfringens from the same enzyme of the Varshavskiy-preparations, above all may be conditioned by the aging of the living culture (18 instead of 5 - 6 hours), as well as by dry preparations (more than 8 years). There are 3 figures, 1 table, and 10 references, 4 of which are Slavic.

45. PURIFICATION OF DIAMINE OXIDASE BY ELECTROPHORESIS (Russian text) - Uspenskaya V. D. and Gorischenkova E. V. Inst. of Biol. and Med. Chem., Acad. of Med. Scis of the USSR, Moscow - BIOKHIMIYA 1958, 23/2 (212-219) Graphs 3 Tables 1 Illus. 1

A simple device is described for electrophoresis on starch. By combining the salt precipitation method with subsequent electrophoretic fractionation, diamine oxidase (DO) from pig kidneys was purified 700 times and DO from pea sprouts 550 times. The purified DO solutions are very labile. The method of zone electrophoresis disclosed some drastic differences in electrophoretic mobility of DO from pig kidneys and pea sprouts: in 0.05 M phosphate buffer, pH 7.2 at 0° u for DO from pig kidneys was -7.9×10^{-5} sq. cm. sec.⁻¹ V⁻¹ while for DO from pea sprouts u was -0.7×10^{-5} sq. cm. sec.⁻¹ V⁻¹.

TITLE: Formation of free porphyrins by green photosynthesizing bacteria

SOURCE: AN SSSR. Doklady*, v. 157, no. 3, 1964, 678-680

TOPIC TAGS: photosynthetic bacteria, porphyrin, photosynthesis, chlorophyll, Chloropseudomonas, Chlorobium, bacterioviridin

ABSTRACT: The mechanism of the biosynthesis of bacterioviridin has not been previously established. To investigate this mechanism, Chloropseudomonas ethylicum and Chlorobium thiosulfatophilum were anaerobically cultured at 30C under 600 lux of illumination. The biomass was determined turbidimetrically with a conversion to dry cell weight. The quantity of bacterioviridin in the cells was determined with an SF-4 spectrophotometer in an acetone-methanole extract. The porphyrin composition in the culture medium was determined as a function of the absorption value in Soret's maximum range (380—430 mμ). The forms and isomeric compositions of the porphyrins were determined

Card 1/3

ACCESSION NR: AP4042798

by paper chromatography and electrophoresis. Quantitative calculations of porphyrins were conducted according to formulas for copro- and protoporphyrin. A study of the culture mediums of both green bacteria cultures revealed that both varieties liberated significant quantities of free porphyrins (up to 1200 ug/g dry cell weight). In this respect green bacteria are similar to purple bacteria. Green bacteria differed from purple bacteria in that the qualitative composition of free porphyrins was always uniform and coproporphyrin (isomer I and III) was present. Purple bacteria liberate coproporphyrin and only traces of other porphyrins. It was shown that the increased liberation of free porphyrins by green bacteria was a function of iron deficiency in the culture medium which inhibited the growth and synthesis of bacterioviridin. The author concluded that under conditions favorable for the synthesis of bacterioviridin, porphyrin liberation by green bacteria decreases. Orig. art. has: 3 figures and 1 table.

TITLE: Separation of two chlorophylls of green bacteria with chromatography

SOURCE: AN SSSR. Doklady, v. 167, no. 3, 1966, 702-705

TOPIC TAGS: bacteriology, paper chromatography, chlorophyll

ABSTRACT: The authors attempted to find a simple method of separating chlorophylls of green bacteria and of comparing the properties of the second chlorophyll of these organisms with the properties of bacteriophyll of purple bacteria. They discovered that green bacteria, along with bacterioviridine, contain a small amount of bacteriophyll. These pigments can be separated by paper chromatography in an isopropanolbenzene system (boiling point 90-110°) and column chromatography with various absorbents (aluminum oxide in stage II of activity, saccharose, polyethylene) if concentrated extracts of the pigments of green bacteria are used. This article was presented by Academician V. N. Shaposhnikov on 18 May 1965. Orig. art. has: 4 figures. [JPRS: 36,932]

Studies on microorganisms causing the appearance and disappearance of odors and tastes in water. L. S. N. Skadovskii, M. A. Messireva, and V. I. Uspenskaya (M. V. Lomonosov State Univ., Moscow). *Trudy Vsesoyuz. Gidrobiol. Obshchestva Akad. Nauk S.S.S.R.* 6, 23-37 (1955).—The factors causing the sporadic appearance of a soil-like odor in waters were studied by using *Actinomyces*, *Oscillatoria splendida*, and *O. agardhii*. With *Actinomyces* the odor was decreased or eliminated by proper aeration and an abundant source of N. It increased in the presence of certain polysaccharides, including starch. *O. splendida* gave the odor when the cells were damaged mechanically, dried, or frozen. Insufficient NO_3^- also caused the appearance of odors. In *agardhii* gave a grassy smell under unfavorable conditions—accumulation of wastes, insufficient N supply, lack of Fe^{++} , etc. The acrid taste imparted to water by this organism under natural conditions disappears in the presence of added NO_3^- and an org. C source. The odorous gas produced by *Actinomyces* could be used as the sole source of C by other organisms growing in the water and soil. The periodic disappearance of odor from waterways was attributed to these organisms, all strains of *Pseudomonas*. Eight strains were isolated. All were facultative anaerobes and could also grow well on meat ext. and potato media. They were found to cause disappearance of odors from lab. cultures and natural sources even when the odor was in high concn.

Title : Preliminary Observations and Experiments in Weakening and
Eliminating Earth Smells in River Water.

Orig Pub : Byul. Mosk. o-va ispyt. prirody. Otd. biol., 1957, 62, No 1,
43-49

Abstract : Laboratory experiments showed that earth smells (ES) or
river water which are caused by the development of Actinomy-
ces and Oscillatoriae [algae] may be prevented from emerg-
ing by decreasing the water's content of organic matter. For
this purpose it is recommended to submerge latticed nets
made of tinned iron with holes measuring about 2-4 mm, upon
which waterplants and bacteria gather and become fastened.
Timely removal of these growth prevent emergence of ES. If

water which contains ES already is let through nets with growths upon them (experiments made in aquaria), ES intensity is lowered significantly. Decrease or complete disappearance of ES takes place at the expense of oxidization processes (experiments made in light and in the dark), which are influenced by O₂ discharged by growth biocoenoses in the process of photosynthesis. The most intensive decrease of ES is attained by growths of pondscum (Spirogyra) algae and by blue-green waterplants. As water with ES is artificially aerated (by being shaken or mixed), absorption of ES is performed by contact with biocoenoses in growth biocoenoses. Capacity of absorption is not only related to the amount of growth, but also to its composition. -- L. A. Azova.

TITLE: New Data on the Geology of the Upper Crimea (Novyye dannyye
po geologii Gornogo Kryma)

PERIODICAL: Byulleten' Moskovskogo obshchestva ispytateley prirody, Ot-
del geologicheskoy, 1958, Vol 33, Nr 1, p 156 (USSR)

ABSTRACT: The authors sum up the report read on 26 November 1957 in
the geological section of the Moscow Society of Naturalists.
The elevation of the south western part of the Upper (Gornyy)
Crimea occurred before the Cretaceous period, and it was
subjected to a deep erosive process. The eroded relief was
then submerged by the sea and filled with argillaceous se-
diments of the Valangian stage. Before the Aptian stage
the elevation reoccurred, succeeded by a new submersion,
and Aptian rocks occur in the depressed parts. The Middle-
and Upper Albian deposits occurring in the base of the Upper
Cretaceous complex also bear traces of erosion.

TITLE: On the Character of the Correlation Between the Lower Cretaceous and Upper-Jurassic Deposits in the South-Western Part of the Gornyy Crimea. (O kharaktere vzaimootnosheniya nizhnemelovykh i verkhneyurskikh otlozheniy v predelakh yugo-zapadnoy chasti Gornogo Kryma)

PERIODICAL: Byulleten' Moskovskogo obshchestva ispytateley prirody, Otdel geologicheskii, 1958, ^{№ 133} Nr 5, pp 81 - 90 (USSR)

ABSTRACT: The article deals with geological research on the correlation of the Lower-Cretaceous and Upper-Jurassic deposits in the south-western part of the Gornyy Crimea, especially in the basin of the Chernaya River. The authors found that ~~Wangian-Hauterivian~~ rock formations fill the deeply eroded depressions in the ~~Kimmeridge~~-Tithonian rocks. The character of the Lower-Cretaceous deposits on the underlying Upper-Jurassic rocks, shows that after the formation of the ~~Kimmeridge~~-Tithonian layers, the whole region underwent a sharp elevation process and was subjected to an active erosion on the earth surface. The intensity of these

Card 1/2

SOV/5-58-5-6/20

On the Character of the Correlation Between the Lower Cretaceous and
Upper-Jurassic Deposits in the South-Western Part of the Gornyy Crimea.

erosive processes in specific parts could be explained only by the heterogeneity of the ~~Kimmeridge~~-Tithonian stratum, composed of rocks of different resistance to erosion. In particular, the deepest basin was formed in the limits of the present Baydar valley, this part having been filled with flysh formations. The basin of the Varnaut valley was also formed in this way. In the following transgression, at the beginning of the Lower-Cretaceous period, the whole region again disappeared under the sea with such speed that the sea did not smoothen the eroded surface which was then filled with the Valangian-Goterive argillaceous deposits. The following geologists are mentioned by the author: A.G. Glukhov, M.V. Churinov, S.N. Mikhaylovskiy, G.Ya. Krymgol'ts, G.F. Veber, V.V. Drushchits, M.S. Eristavi, M.V. Muratov and I.M. Tsypina. There are 2 drawings, 1 map, 3 diagrams and 15 references, 14 of which are Soviet and 1 Swiss.

TITLE: Determining the thermal stability^{//} of lubricating greases^{//}

SOURCE: Metody otsenki ekspluatatsionnykh svoystv reaktivnykh topliv i smazochnykh materislov (Methods for the performance evaluation of jet propellants and lubricants). Moscow, Izd-vo Mashinostroyeniye, 1966, 104-109

TOPIC TAGS: grease, lubricant property, heat resistance, THERMAL STABILITY, LUBRICATING OIL

ABSTRACT: The new method worked out for determining the thermal stability of lubricating greases is based on determining the length of time the grease is heated at a given temperature to complete dryness, and the effect of atmospheric oxygen on it. The proposed method was found sufficiently accurate for temperatures of 120-350°C. The method clearly shows the effect of temperature on thermal stability of different greases and helps to differentiate between greases of different compositions according to their thermal stability. It was established that volatility alone cannot be used as a characteristic of thermal

TITLE: Evaluating the work capacity of greases used in ball bearings

SOURCE: Metody otsenki ekspluatatsionnykh svoystv reaktivnykh topliv i smazochnykh materialov (Methods for the performance evaluation of jet propellants and lubricants). Moscow, Izd-vo Mashinostroyeniye, 1966, 118-125

TOPIC TAGS: lubricant, ball bearing, grease

ABSTRACT: Experimental data are given on a new method for comparative evaluation of the work capacity of greases used in high-speed closed roller bearings operating at temperatures below 350°C. Duration of normal bearing operation is used as the criterion for evaluating the work capacity of the lubricants. The point of binding is assumed as the breakdown point of normal bearing operation. Binding is characterized by disruption of smooth bearing operation and by a significant temperature increase in the external ring. 7VP180506BT3 ball bearings were tested on the IS-9 unit. Several bearings belonging to a single precision class were used for each testing stage. These bearings were washed in benzene and acetone before testing, and the clearances between the rings and separators were filled with the lubricant to be tested. 1.5 and

3 g of lubricant were used throughout the tests for each bearing. The bearings were tested at 5000 and 10,000 rpm and 200 and 350°C with a radial load from 50 to 450 kg. The tests were arranged in five-hour sequences. A diagram is given showing the test equipment and bearing specimen. The proposed method may be used for accurately determining the nominal work capacity of greases by testing them on 3-5 bearings. The results show that the nominal work capacity of TsIATIM-221¹ grease is 13 hours, while that for VNII NP-222-2¹ lubricant is 1 hour at 500 rpm, 250°C bearing temperature and a radial load of 250 kg. The nominal work capacity of VNII NP-235 grease is 32.1-46.4 hours, while that for standard TsIATIM-221 lubricant is 31.1-58 hours at 10,000 rpm and a radial load of 150 kg at 250°C and 200°C respectively for the two lubricants. VNII NP-222-2 and VNII NP-206 lubricants showed a similar work capacity under identical conditions. This method for determining the nominal work capacity of greases should find application in further research work. Orig. art. has: 3 figures, 2 tables, 1 formula.

POLY SILOXANE

ABSTRACT: This Author Certificate introduces a method for preparing liquid polyorganosiloxanes. To increase high-temperature oxidation resistance and the lubricating property because of introducing fluoroalkyl and fluoroaryl radicals into the polymer structure in both the end groups and the basic chain, liquid polyorganosiloxanes are prepared by either cohydrolysis or heterofunctional condensation of corresponding monomers. [LD]

Concetti and Rossler, a modification of T. M. Turpayev's technique, during artificial respiration of the animal after injection of ditieline, a curare-simulant preparation (succinic acid dimethyl-aminoethanol ester diiodomethylate). For most of the preparations, the minimum doses which relieved bronchospasm coincided with the doses which prevent a depressive effect during irritation of the peripheral section of the vagus nerve, but were considerably lower than the doses which remove depressive effects of the intravenously injected acetylcholine. This shows that the function of the preparations investigated depend for their blocking effect on the ganglion of the pulmonary branches of the vagus nerve, and, as a result, they temporarily check its influence on the bronchia. -- L. S. Romanova.

PROCESSES AND PROPERTIES INDEX

The decomposition of the green parts of lupine in the soil. Z. P. Uvarovskaya. *Udobrenia i Urozhai (Fertilizers and Crops)* 2, 635-8(1930).—Green lupine in the blooming stage was added to 5 kg. of soil at the rate of 100 g. and 200 g., which was equal to 5.0 and 1.0 g. of N. Another series was prepd. to which 0.5% CaCO_3 was added.

Pptd. phosphate and raw phosphates were used as the source of P. The plant used was millet. The soil was a podsolized loam. The course of the decompn. of lupine in soil was followed simultaneously with the pot expts. The 100-g. application of lupine gave just as good results as those obtained with $(\text{NH}_4)_2\text{SO}_4$; the 200-g. application gave a higher yield. The lime with the 100-g. application gave just as good results as the 200-g. application alone. Lupine with $(\text{NH}_4)_2\text{SO}_4$ gave the highest yield. The amt. of org. matter increased, but the increases with the 100- and 200-g. applications were the same. The pH of the ext. decreased because of formation of the acids. The amt. of absorbed NH_4 increased more in the soils in which lupine was used than in the soils which received $(\text{NH}_4)_2\text{SO}_4$. Composites of lupine at the rate of 5 and 10 g. of lupine for 200 g. of soils were prepd. These were sampled after 10, 20, 35, 60 and 85 days. The reaction became more alk. on account of NH_4 formation. The nitrate content in the first period decreased, with or without addns. of lime. From the third period on the nitrates appeared in the soils without lime. With the lime, nitrification was decreased. In all cases there were considerable amts. of NH_4 , especially with the lime. With the increase in nitrate content the amt. of absorbed NH_4 decreased.

TITLE: Producing a Eutectic Potassium-sodium Alloy (Polucheniye kaliy-natriyevogo splava evtekticheskogo sostava)

PERIODICAL: Tr. Ural'skogo n.-i. khim. in-ta, 1957 (1958), Nr 5, pp 91-98

ABSTRACT: An investigation was made of a method of producing a eutectic K-Na alloy without organic additions (paraffin, kerosene, oil), and containers for storage and transport are designed. The process is conducted in airtight equipment consisting of a retort 180 mm high, 75 mm in diameter and 2 mm in wall thickness. Before the experiment, pieces of Na and K were freed of kerosene and oil by filter-paper pressure. The surface film of oxide was then cut away, and samples calculated to contain 22 weight % Na and 78 weight % K were then prepared in a dry, closed box. The K was placed on the bottom of the retorts, and the Na atop the piece of K. Then a vacuum (residual pressure 0.05 mm Hg) was created in the retort and the receiver. The metal was heated to 70-80°C, stirred, and poured

Card 1/2

SOV/137-58-8-16745

Producing a Eutectic Potassium-sodium Alloy

into the receiver after cooling to room temperature. To separate the films from the alloy, the metal was filtered through an Fe screen with ~1-mm mesh, the screen being pulled over a tripod installed in the retort. The K and Na were placed on the screen. With heating the metal melted and flowed onto the bottom. The resultant alloy cast to a mirror-smooth surface. Airtight containers were developed and tested for the production, storage, and transportation of the K-Na alloy.

TITLE: The Replacement of Hydrochloric Acid by Sulfuric Acid in the Production of Elemental Boron

PERIODICAL: Tr. Ural'skogo n.-i. khim. in-ta, 1957 (1958), Nr 5, pp 222-227

ABSTRACT: The results of laboratory and semi-industrial experiments are submitted which showed that in the production of elemental B by reduction of boracic acid with Mg metal (RZhKhim, 1959, 1824) for the lixiviation of MgO from the sinter commercial contact H_2SO_4 can be used (instead of HCl acid). The cost of B is hereby reduced by 10% and working conditions are improved as a result of less gas liberated. The balance of materials in the production of B is submitted, when using H_2SO_4 for lixiviation.

Oxidation of amino acids by tissues of various plants.
V. L. Kretovich and Zh. V. Voznesenskaya. *Doklady Akad. Nauk S.S.S.R.* 82, 951-4 (1963). — Ten-day-old pea sprouts, ground with sand and phosphate buffer, were tested manometrically with a substrate of various amino acids by using the Warburg technique for detn. of oxidation of the latter (C.A. 43, 2283e). Aspartic acid is oxidized $\frac{1}{2}$ as fast as glutamic; the dicarboxylic amino acids are oxidized most rapidly at pH 8.33, and an increase in the concn. of pea-tissue suspension increases the reaction rate: max. rates occur at optimal concns. of the acids (0.06-0.1 M for glutamic and 0.045 M for aspartic acids). Etiolated pea sprouts cause much slower oxidation than green ones (factor about 1.5). Sunflower-sprout tissue has very little oxidative effect on glutamic acid. Oxidation in the presence of polyphenoloxidase of the sunflower in the presence of pyrocatechol gave the following descending order of oxidizability: glycine, L-glutamic acid, L-leucine, DL-methionine, DL-alanine, L-histidine, L-tyrosine, L-aspartic acid, L-proline, and L-tyrosine. Chlorogenic acid derived from sunflower is effective in such oxidations but its activity is less than 50% of that of polyphenoloxidase. G. M. Kosolapoff

A method for isolation of chlorogenic acid from sunflower seeds. V. L. Kretovich and Zh. V. Uspenskaya (A. N. Bakh Inst. Biochem., Acad. Sci. U.S.S.R., Moscow). *Biochim. Zerna Akad. Nauk S.S.S.R., Sbornik* 2, 203-7 (1954).—Seeds (2.5 kg.) freed from husks are pressed in a hydraulic press, and the fat residue is extd. 5 times from the solids with Et₂O. The air-dried solid is then extd. 3 times with hot 70% EtOH for 5 min.; the cooled slr. ext. is cooled and filtered, and the ppt. is discarded. The filtrate (7.1 l.) is treated with 5 ml. Pb(OAc)₂ (40% soln.) until cloudiness forms and the yellow-green ppt. is sepd. and discarded. The filtrate is treated with 250 ml. 40% Pb(OAc)₂; the yellow ppt. is centrifuged off, washed with warm 70% EtOH, stirred with 60 ml. H₂O, and treated with 250 ml. 6% H₂SO₄; the PbSO₄ is sepd. and the filtrate is extd. 8-10 times with 200 ml. EtOAc. The evapd. ext. is dried, evapd. to 60 ml., and chilled. The crude product is recrystd. from H₂O and dried *in vacuo*, yielding 4 g. chlorogenic acid, m. 206° (cf. Gortler, *C.A.* 4, 447). G. M. K.

Absorption spectra and rearrangement of groups in geometrical isomeric complex compounds of cobalt. A. Uspenskii and A. Hamdas. *Trans. Inst. Pure Chem. Res. agents* (U. S. S. R.) No. 13, 48-54 (1933).—The absorption spectrum of a complex having a colorless anion and a colored cation is detd. by the latter. The anion affects only to a small degree the value of the absorption coeff. The absorption of light by complexes said. in respect to the coordination no. obeys to a larger or smaller degree Lambert-Beer's law in solns. of 0.01-0.005 *N*. The absorption spectra of one group of the stereoisomeric complex pairs are characterized by the fact that the max. light absorption of the *cis*-isomer on a diagram almost corresponds to the min. of the *trans*-isomer, while the second group, being small in no., is characterized either by an identity of absorption spectra in the visible region or by their similarity. Groups like HBr , H_2O and others, attached to the outer sphere of the complex do not affect the absorption spectra in the visible region. The investigation of absorption spectra of the stereoisomers is drawn in regard to the intramol. re- W. P. Erickson

isomeric dibromides permits a conclusion to be drawn in regard to the intramol. re-
arrangements and the reaction mechanisms which take place.
